20. ABSTRACT (Cont'd)

Breakdown Rate Analyzer (COBRA) values and microscopic examination for microbiological activity.

This study has shown that the two parameters most effecting long-term storage of turbine lubricants are temperature and free water or high humidity. As the storage temperature increases, the rate of lubricant hydrolysis rapidly increases with hydrolysis being the major mechanism for lubricant degradation under these conditions. One MIL-L-7808 fluid showed superior stability in comparison to the other fluids but not of sufficient degree to provide 16 months storage under high moisture conditions at 100°F. Microbiological activity did not effect the rate of lubricant degradation significantly.

PREFACE

This technical report was prepared by the Lubrication Branch, Fuels and Lubrication Division, Aero Propulsion Laboratory (APL), Air Force Wright Aeronautical Laboratories (AFWAL), Air Force Systems Command, Wright-Patterson Air Force Base, Ohio. The work herein was accomplished under Project 3048, Task 304806, Work Unit 30480626, "Turbine Engine Lubricant Research," during the period of June 1979 to November 1980 with Mr H. A. Smith as Project Engineer. Special acknowledgement is given to Mr M. A. Schumacher, AFWAL/POFF, for his outstanding contribution to this effort.

SECTION I

INTRODUCTION

The storage of turbine lubricants in normally used containers such as hermetically sealed quart cans or drum stock utilized through use of servicing carts is satisfactory with respect to long-term lubricant stability. Current lubricants possess good low temperature oxidative, thermal and hydrolytic stability under these conditions of storage which is of relatively low temperatures and limited oxygen availability. Water content of new lubricant is also low and usually below 500 ppm.

For turbine lubricants (ester base) to be stored under these conditions, lubricant storage stability can be predicted using the SOD lead corrosion test. Specification MIL-L-7808 requires lubricant stored in hermetically sealed containers to conform to all specification requirements after three years of storage. Specification MIL-L-23699 requires hermetically sealed containers of the lubricants to conform to specification requirements after one year of storage.

In normal turbine engine lubricant systems, lubricant storage stability is not a problem due to frequent usage, oil consumption and replenishment, and a very low water or humidity environment.

The use of ester type lubricants under conditions which are not typically associated with turbine engines is increasing due to new applications and new lubricant system requirements. Some advanced systems employing ester base lubricants require storage capability under adverse conditions such as non-Hermetically sealed dormant systems for time periods of two years or more.

A lubricant sample obtained from such a system after 18 months storage showed severe degradation and contained large quantities of both motile and non-motile microorganisms. Although the lubricant contained no free water or suspended water, the presence of bacteria suggested free water may have been present somewhere in the lubricant system. The question which remained unanswered after the completion of the analyses

was what caused the severe lubricant degradation. Possibilities include low temperature oxidation, hydrolysis, microbiological activity, or a combination of these possibilities. Since no information existed relative to lubricant storage characteristics under adverse conditions, a program was initiated for investigation of the storage capability of current turbine lubricants under these conditions.

The objectives of this study was to investigate differences long-term storage characteristics of current lubricants under var is storage conditions and the effect of microorganisms on lubricant degradation causing increased acidity of the lubricant.

SECTION II

TEST EQUIPMENT AND PROCEDURES

1. GENERAL

The test program was designed to investigate six lubricants at two temperatures using different types of containers under various environments. This resulted in five major test systems as shown below.

- Test System A. Closed system with free water.
- Test System B. Open system with 100% relative humidity.
- Test System C. Control systems with closed and open containers.
- Test System D. Open and closed systems with free water and innoculated.
- Test System E. Open and closed systems with 100% relative humidity and innoculated.

Table 1 shows a diagram of the test program.

2. TEST EQUIPMENT

The storage containers used for the test program included the following.

- a. Sixteen ounce capacity flint glass bottles with Poly-Seal screw caps.
- b. Four ounce capacity flint glass bottles with Poly-Seal screw caps.
 - c. One hundred fifty milliliter capacity Pyrex beakers.
- d. Sixteen ounce plain tin F style oblong cans with one inch screw caps.

Sealed desiccators were used for obtaining 100% relative humidity test chambers. A horizontal air-flow mechanical connection oven was used for the tests conducted at $100^{\circ}F$ (37.8°).

TEST PROCEDURES

The test samples were prepared and coded as shown in Tables 1 and 2. Closed system samples were sealed with caps while open system samples were stored uncapped. Samples containing free water were prepared by adding the test lubricant to containers having the free water without mixing. Sample containers were stored in desiccators containing free water below the desiccator plate for the 100% relative humidity testing. All of the 108 lubricant test samples were stored in the dark except for the brief periods of sampling or visual observations. Forty-eight of the samples were stored at room temperature in a steel cabinet. The remaining 60 samples were stored at 100° F in the mechanical connection oven. No sterilization of any containers or fluids was done prior to testing.

TESTING AND EVALUATION CRITERIA

The stored samples were periodically analyzed using the following test procedures and evaluation criteria.

a. Total Acid Number Measurements

The total acid number of lubricants is the quantity of base, expressed in milligrams of potassium hydroxide required to neutralize all acidic constituents present in one gram of the oil. These determinations were conducted using ASTM Method D664, "Neutralization Number by Potentiometric Titration."

b. Complete Oil Breakdown Rate Analyzer (COBRA) Measurements

The COBRA is an electronic instrument that measures the electrochemical characteristics of the lubricant. Lubricant degradation increases the electrochemical characteristics which are measured by

changes in the COBRA readings. New lubricants have COBRA values below 10 while highly degraded lubricants have values of 150 or above.

c. Visual Appearance and Odor

The visual appearance and odor of a lubricant can provide information relative to its condition. Visual appearance can give information relative to free water content, degradation and sedimentation, and microbiological activity. Odor characteristics can also indicate lubricant condition. Synthetic turbine lubricants having strong rancid odors usually exhibit high levels of degradation.

Terms used in describing the visual appearance of the lubricants are as follows:

<u>Clear and Bright</u> - The lubricant is transparent, has a bright appearance and no visible suspended sediment.

<u>Transparent</u> - Darkening of the lubricant but still capable of transmitting light so objects or images can be viewed through the lubricant.

Slightly Cloudy - Slight haze but not completely translucent.

Cloudy - Completely translucent.

Opaque - Very dark in color. No light transmittance.

<u>Sediment</u> - Visible material that settles to the bottom of the sample or visible particles suspended in the sample.

<u>Scum</u> - A film layer of materials that forms on or rises to the surface of the sample or at the interface of the oil-free water samples.

Terms used in describing the odor of the lubricants are as follows:

Sweet - Normal new oil odor.

Semi-Sour - Slight offensive odor.

Sour - Strong offensive odor.

<u>Rancid</u> - Very disagreeable offensive odor. Containers containing this type of degraded lubricant cannot be left open in the laboratory due to its strong rancid odor.

d. Microscopic Examination for Microorganisms

Phase contrast microscopy was used for the microscopic examination of the various samples. Small quantities of the lubricant, scum or water were withdrawn from the storage containers by means of a disposable pipet and placed on microscope slides. Cover slides were used for all examinations which were made at 200X, 400X, and 800X magnification. No attempt was made to identify or classify the types of microorganisms observed.

SECTION III

TEST LUBRICANTS

Six lubricants were evaluated in the program with all being ester base lubricants. Table 2 presents a description of these unused lubricants.

TABLE 2

DESCRIPTION OF TEST LUBRICANTS

TEST OIL NUMBER	QUALIFICATION NUMBER	DESCRIPTION				
1	1M-1	MIL-L-7808 J Lubricant				
2	1N-1	MIL-J-7808 Lubricant				
3	15E-1	MIL-L-7808 J Lubricant				
4	11E-1	MIL-L-7808 J Lubricant				
5	0-9A-4	MIL-L-2369 C Lubricant				
6	1M-1 Plus Corrosion Inhibitor	MIL-L-7808 J Plus Barium Dinonylnaphthalene Sulfonate				

Lubricant coded OP-172-1 was also used to innoculate the above lubricants for specific phases of this program. Prior analysis of this lubricant was as follows:

Total Acid Number: 24

Viscosity @100°F 13.57 cs

Gas Chromatography: MIL-L-7808, Qualification Number 1M-1 Chromatogram showed indications of oil degradation.

Phase Contrast No dispersed silicone or suspended water. Large number of motile and non-motile microorganisms present.

SECTION IV

TEST RESULTS AND DISCUSSION

Evaluation of the test lubricants were made at various intervals during the storage program. Visual appearance and odor evaluations were made initially and at 1, 2, 3, 6, 11, and 16 month storage periods. COBRA readings were conducted on the same schedule as that for appearance and odor. Total acid number measurements were made initially and at 6 and 16 month storage periods. Microbiological evaluations were conducted only at the end of 11 months storage. The evaluation data is presented in Tables 3 through 56.

The effect of test conditions at $100^{\circ}F$ was consistent for all the MIL-L-7808 lubricants and the MIL-L-23699 lubricant. The various test systems are listed below in order of decreasing severity.

- 1. Open glass beaker, 100% humidity innoculated with OP-172-1 (only slight more severe than 2 below).
- 2. Open glass beaker, 100% humidity (significantly more severe than 3 below).
- 3. Closed glass bottle, free water, innoculated with OP-172-1 (only slightly more severe than 4 below).
- 4. Closed glass bottle, free water (significantly more severe than 5 below).
- 5. Open glass bottle, free water innoculated with OP-172-1 (extremely more severe than 6 below).
- 6. Open metal container (6 through 10 exhibited only very slight differences).
 - 7. Closed glass bottle, innoculated with OP-172-1.

- 8. Open glass bottle
- 9. Closed metal container.
- 10. Closed glass container.

The obtained storage stability data shows the two most significant variables effecting lubricant storage is temperature and water. At 70°F, all conditions of storage were satisfactory for 16 months of storage. At 100°F, all storage conditions involving free water or 100% relative humidity caused excessive lubricant degradation prior to six month storage except for MIL-L-7808 lubricant, Qualification Number 11E. This lubricant demonstrated superior hydrolytic stability but still was not satisfactory for 16 months storage under these conditions. Very little difference was found among the various storage conditions not involving free water or high relative humidity. Changes in total acid number values and COBRA values showed very similar trends for all test fluids.

The various storage conditions at 100°F are listed below in order of decreasing severity for the MIL-L-7808 fluid containing the corrosion inhibitor.

- 1. Closed glass bottle, free water, innoculated with OP-172-1 (only slightly more severe than 2 below).
- 2. Closed glass bottle, free water (only slightly more severe than 3 below).
- 3. Open glass beaker 100% relative humidity, innoculated with OP-172-1 (only slightly more severe than 4 below).
- 4. Open glass beaker, 100% relative humidity (significantly more severe than 5 below).

- 5. Open glass bottle, free water, innoculated with OP-172-1 (extremely more severe than 6 below).
- 6. Open metal container (6 through 10 exhibited only very slight differences).
 - Closed metal container.
 - 8. Closed glass bottle innoculated with OP-172-1.
 - 9. Open glass bottle.
 - 10. Closed glass bottle.

This specific fluid is very similar to the other MIL-L-7808 and MIL-L-23699 fluids in that temperature and the presence of free water or high humidity are the most significant variables effecting storage. The major storage stability difference in the fluid containing the corrosion inhibitor is the free water showing a greater effect than the 100% relative humidity. This was reversed for the MIL-L-7808 and MIL-L-23699 fluids.

The presence of microorganisms did not significantly effect storage stability. As would be expected, only those systems having free water or high humidity exhibited microbiological activity. No significant difference in microbiological activity was observed for testing conducted at 70°F and 100°F . All fluids appeared similar in support of microbiological growth except the MIL-L-23699 lubricant. This specific formulation may possess some microbiological inhibitor characteristics. Although this fluid exhibited low hydrolytic stability and no microscopic examinations were made on storage tests conducted at 100°F , the microscopic examinations on all 70°F storage samples of this lubricant showed no microbiological activity while all the other fluids showed some support for microbiological activity at this temperature.

All fluids formed a scum or emulsion at the oil-water interface for those systems containing free water. Formation of these scums or emulsions did not require microbiological activity for all lubricants investigated.

SECTION V

CONCLUSIONS AND RECOMMENDATIONS

This study has shown that the two parameters most effecting long-term storage of turbine lubricants in non-sealed systems are temperature and free water or high humidity. As the storage temperature increases, the rate of lubricant hydrolysis rapidly increases and is the major mechanism for lubricant degradation under these conditions. One MIL-L-7808 lubricant showed superior hydrolytic stability in comparison to the other test lubricants but not of sufficient degree to provide 16 months storage under high moisture conditions at a temperature of 100°F.

Microbiological activity did not significantly effect the rate of lubricant degradation. The presence of microbiological activity did, in some cases, contribute to the scum, sludge and emulsions forming at lubricant-water interfaces. This type of material has the capability of plugging small oil orifices or filters.

The corrosion inhibited fluid consisting of a MIL-L-7808 fluid plus barium dinonylnaphthalene sulfonate showed less storage stability than the other lubricants and did not display any microbiological inhibiting characteristics.

Future development of ester type lubricants for use under conditions of high humidity and long-term storage should include studies for improving the hydrolytic stability of current turbine engine lubricants.
